
(a) Constructed-request evaluation
Shared configured topology and roles → fixed structural calculation and role-object endpoints
Normal-only training
200 req/s × 600 s
Separate fit for every stream
Fit transition parameters
Role-wise transition matrix
and sequence endpoints
Use only the paired fit
Each calibration stream and
evaluation have their own fit
Three calibration streams
120000 requests per stream
Seed offsets +101, +202, +303
Structural threshold selection
Own FPR ≤ 0.12; detect A1/A3
All three select θ = 0.30
Save and freeze thresholds
θstruct = θtrans = 0.30
Transition θ shared by design
Distinct evaluation stream
120000 requests; seed offset +3
Separate normal-only training fit
Apply saved thresholds
No selection on evaluation
Report alerts and first disposition
Decision-function timing
Begins after inputs are available
No credential or ledger wait
Timing is a separate measurement
(b) Separate evidence paths
Numerical model checks → interval relation, Eq. (13)
Four-node chain → gas, throughput and confirmation
